Marine Corps Installations East-Marine Corps Base Camp Lejeune Wastewater Collection System

AWWTP Overall Performance

Summary of Violations ...

Wastewater Collection System - Public Reportable Spills

During the monitoring period of record there was one reportable sewage overflow (spills). A summary is listed below:

Reportable Sewage Overflows (spills)

Estimated

Volume (gal.) Surface Water Reached

Location of Spill

Reason for Spill

Parking lot area (corner of Burger King) at intersection of McHugh & Gonzalez Blvd's

Break in pipe

Definitions

mg/L (milligrams/Liter) are the units of concentration used to express environmental measurements. 1 mg/L is equivalent to 1 part per million (ppm). You can think of 1 ppm as 1 cent in \$10.000.Á

Influent - wastewater entering the treatment plantÁ

Effluent - wastewater leaving the treatment plantÁ

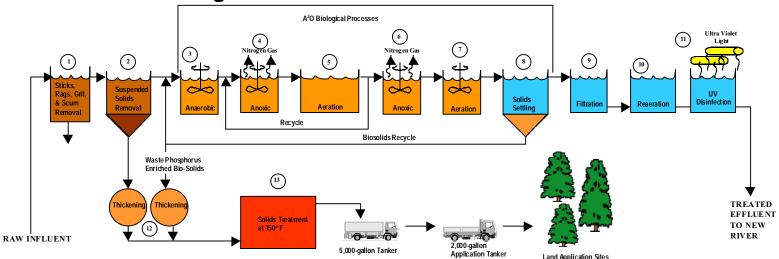

BOD (Biochemical Oxygen Demand) is a pollution indicator. It is a measurement of the dissolved oxygen needed by microorganisms to biologically degradeÁ pollutants. The normal BOD test is conducted during a 5 day laboratory period and denoted BOD $_{\rm s}$. Raw domestic sewage typically has a BOD $_{\rm s}$ of about 200Á mg/L whereas a typical BOD $_{\rm s}$ of unpolluted surface water would be less than 5 mg/L. If discharged to the environment, water with an elevated BOD couldÁ deplete (use up) the dissolved oxygen in rivers and streams due to the biological degradation of the pollutants by naturally occurring microorganisms. ThisÁ can cause fish kills and septic conditions.Á

TSS (Total Suspended Solids) is a pollution indicator. It is simply a measurement of undissolved solids. Similar to BOD, raw domestic sewage typically hasÁ a TSS of about 200 mg/L. If discharged to the environment, elevated levels of TSS can produce sludge deposits and cause septic conditions.Á

Ammonia Nitrogen (NH₃-N) represents the concentration of nitrogen bound in the ammonia form. Raw domestic sewage typically has an NH₃-N ofÁ about 15 to 20 mg/L. If discharged to the environment, elevated levels of NH₃-N can cause three problems. These include: (1) depletion of dissolvedÁ oxygen in rivers and streams because the biological degradation of ammonia is an oxygen consuming process, (2) impairment and death to fish and otherÁ aquatic organisms due to the direct toxicity of ammonia, and (3) increased growth of algae due to the nutrient effects of nitrogen.Á

Phosphorus is an essential nutrient for all biological growth. However, if discharged to the environment, elevated levels can cause excessive growth of A algae and other aquatic plants. The subsequent decay of these plants can result in a depletion of dissolved oxygen. Á

Treatment Plant Diagram

GENERALIZED WASTEWATER TREATMENT PLANT (WWTP) PROCESS DESCRIPTION

The Camp Lejeune Advanced Waste Water Treamtment Plant (AWWTP) isÁ an advanced biological process that consists of three different microbialÁ environments. The combined environments are called the A²O process for A Anaerobic, Anoxic and Oxic. These three zones cultivate a special mix ofÁ beneficial microorganisms that absorb phosphorus and convert chemi-Á cally bound nitrogen to harmless and inert nitrogen gas. Residual phos-Á phorus not absorbed by the microorganisms is removed by chemicalsÁ added by the WWTP's operations staff. Other microorganisms (primarily inÁ the oxic zone) biologically degrade wastewater pollutants by using organicÁ material as food and converting it to new microbes, carbon dioxide andÁ water. All of the three A2O zones consist of mixed slurries of wastewaterÁ and microorganisms. After treatment, the water and microbes are sepa-Á rated by gravity settling in large tanks. The clean water is skimmed from A the surface, filtered, disinfected with ultra-violet light and returned to theÁ New River. The microbes are continuously collected from the bottom of theÁ tanks and returned to the three A²O zones using recycle pumping systems.Á This recycling provides a continuous source of microbes to degrade in-Á coming pollutants. As pollutants are removed, the microorganisms growÁ and multiply. This growth results in the production of excess microorgan-Á isms. These excess microbes are continuously removed (a process calledÁ wasting) to maintain a consistent and optimal balance between availableÁ microbes and the amount of food (pollutants) entering the WWTP. TheÁ

excess microorganisms (called residuals or biosolids) are Á treated at an elevated temperature (±150Å) to kill disease caus-Á ing organisms, to reduce odors and for further treatment of bio-Á degradable pollutants. The treated residuals are applied to ag-Á riculture and forest areas for their beneficial nutrients and soilÁ conditioning characteristics. The flow of water into and out ofÁ the WWTP is a continuous operation — the WWTP operates 24Á hours per day and 365 days per year.Á

Descriptions of the WWTP processes are summarized below:Á

- 1 Preliminary Treatment is merely a screening process that A removes large debris such as sticks, rags, grit and sand. The A removal of these constituents protects downstream equipment.
- **2 Primary Clarification** consists of large tanks where sus-Á pended solids settle to the bottom. The settled solids are trans-Á ferred to the solids treatment process. In general this processÁ removes about 50% of the TSS entering the WWTP influent. TheÁ remaining fraction is either degraded (solubilized) in the biologi-Á cal processes or removed in the WWTP's secondary clarifier.Á

- 3 The Anaerobic Zone is a mixed tank void of dissolved oxygen.Á The absence of all oxygen is conducive to the growth of specialÁ bacteria (*Acinetobacter*) that consume organic acids and releaseÁ stored phosphorus in the anaerobic tank. However, these sameÁ organisms uptake high levels of phosphorus when they enter theÁ aerobic (oxic) zone of the WWTP. Thus, the cycling of the microbesÁ between the anaerobic and oxic environments is the mechanismÁ responsible for enhanced phosphorus uptake. This cycling is ac-Á complished by the normal flow of water and the recycle system thatÁ returns the microbes to the anaerobic zone after they have beenÁ oxygenated in the oxic zone of the WWTP. Phosphorus (a algaeÁ causing nutrient) is ultimately removed from the WWTP by wastingÁ excess microbes after the oxygenated cycle and when stored phos-Á phorus levels are greatest.Á
- **4 The Anoxic Zone** consists of mixed tanks that have essentiallyÁ no dissolved oxygen. However, these tanks do contain oxygen thatÁ is chemically bound to nitrogen in a molecule called nitrate (NO₃-Á N). This nitrate nitrogen is a byproduct from the biological treat-Á ment of ammonia and is introduced to the anoxic zone through theÁ recycle from the outlet of the aeration tank. In the absence of dis-Á solved oxygen, bacteria in the anoxic zone break the chemical bondÁ between the oxygen and nitrogen. The oxygen is used by the mi-Á crobes to produce new bacteria, water and carbon dioxide. MoreÁ importantly, the nitrogen (a nutrient responsible for the growth ofÁ excess algae) is removed from the water and released to the atmo-Á sphere as a harmless and inert gas.Á
- **5 --- The Oxic (Aerobic) Zone** consists of mixed and oxygenatedÁ tanks. Oxygen is supplied from the atmosphere using mechanicalÁ agitators located on the surface of the tanks. In this process, aero-Á bic (oxygen using) and other microorganisms perform the follow-Á inq:Á

Reduce BOD: This is the biological degradation of waste-Á water pollutants. Simply stated, microorganisms consumeÁ organic material for food and convert it to new microbes,Á carbon dioxide and water.Á

Nitrify Ammonia: This is the biochemical oxidation of am-Á monia nitrogen to the much more stable and benign formÁ called nitrate nitrogen (NO₃-N). The benign NO₃-N can beÁ biologically degraded to nitrogen gas when recycled to theÁ anoxic zone of the WWTP.Á

Uptake of Phosphorus: The special bacteriaÁ (*Acinetobacter*) cultivated in the anaerobic zone absorb aÁ significant amount of phosphorus in the aerobic tank. ThisÁ absorbed phosphorus is ultimately removed from the wa-Á ter when excess microorganisms are wasted from theÁ WWTP.Á

- **6 —The Post Aerobic Anoxic Zone** uses the same mechanisms asÁ previously described to convert nitrate to nitrogen gas. This particularÁ zone is simply another location to cultivate special microbes andÁ provide an additional opportunity for these organisms to convert ni-Á trate to inert nitrogen gas.Á
- **7 The Second Stage Aeration Zone** consists of small aeratedÁ tanks. This particular zone is simply used to return dissolved oxygenÁ to the water following the anoxic (oxygen free) process.Á
- **8 Secondary Clarification** consists of large tanks where the sus-Á pended biosolids (microorganisms) are separated from the water;Á the biosolids simply settle to the bottom of the tank. As a general ruleÁ of thumb, approximately 97 to 98% of the biosolids entering the sec-Á ondary clarifier are recycled back to the anaerobic zone so they canÁ treat incoming waste products. About 2 to 3% of these "phosphorusÁ enriched biosolids" are due to the growth of excess microbes and areÁ wasted to the solids treatment process.Á
- **9 Filtration** is a polishing process that removes the trace levels of Á suspended solids that do not settle in the secondary clarifier. This Á process employs a layer of sand that removes the solids by straining Á and adsorbing suspended material. Á
- **10 The Reaeration Process** is a small aerated tank used to in-Á crease the level of dissolved oxygen in the treated water just before itÁ is discharged. This helps maintain a higher oxygen content in theÁ New River in the vicinity of the WWTP's discharge line.Á
- 11 Disinfection is the final process in the WWTP. It is used to killÁ disease causing microorganisms. It is important to note that noÁ chemicals are used in disinfection process at this WWTP biologi-Á cal kills are accomplished using environmentally benign ultravioletÁ (UV) light.Á
- 12 Solids Thickening is used to remove some of the water fromÁ the slurry of waste biosolids. Thickening is used to reduce the vol-Á ume of waste solids and increase the capacity of the WWTP's residu-Á als processing tanks. As a general rule, thickening reduces the vol-Á ume by about 65 to 75%.Á
- 13 Solids Treatment is used to kill disease causing organisms, A reduce odors and for further treatment of the biodegradable pollut-A ants in the biosolids. The process consists of mixed and aerated A tanks operated at about ±150Å. The heat is generated internally A from the biological decomposition of the biosolids by special bacte-A ria that flourish in this type of environment. This process is similar to A composting. A

AWWTP Permit Limits and Performance Data

Permit Limits on AWWTP Effluent				
Parameter ⁻	Monthly Average Limitation (mg/L)			
	April 1 to October 31Á	November 1 to March 31Á		
BOD ₅	54	10		
TSS	30	30Å		
NH ₃ -N	2	4		
Phosphorus	0.5	1		

Parameter	Influent (mg/L)	Effluent (mg/L)	Removed	
		1		
Biosolids Production During the 12 Month Period
